Library of Congress Cataloging-in-Publication Data

Dettmer, H. William.

The logical thinking process : a systems approach to complex problem solving /

H. William Dettmer.

p. cm.

A total re-write, more than a second edition, of his Goldratt's Theory of Constraints, c1997.

Accompanied by a compact disk that contains a full-function, unrestricted copy of version 1.0 of Transformation Logic Tree software.

ISBN 978-0-87389-723-5

1. Decision support systems. 2. Problem solving. 3. Theory of constraints (Management)

4. Decision trees--Computer programs. 5. Industrial management. I. Dettmer, H. William.

Goldratt's theory of constraints. II. Title. III. Title: Systems approach to complex problem solving.

HD30.213.D48 2007

Table of Contents

<i>Preface</i>	<i>xxiii</i>
<i>Acknowledgments</i>	<i>xxv</i>
<i>Introduction</i>	<i>xxvii</i>
PART I – THE DESTINATION	1
Chapter 1 Introduction to the Theory of Constraints	3
Systems and “Profound Knowledge”	4
The System’s Goal	5
The Manager’s Role	5
<i>Who Is a Manager?</i>	5
<i>What Is the Goal?</i>	6
<i>Goal, Critical Success Factor, or Necessary Condition?</i>	6
The Concept of System Constraints	8
<i>Systems as Chains</i>	8
<i>The “Weakest Link”</i>	8
<i>Constraints and Non-constraints</i>	9
<i>A Production Example</i>	9
Relation of Constraints to Quality Improvement	10
Change and the Theory of Constraints	11
TOC Principles	12
<i>Systems as Chains</i>	12
<i>Local vs. System Optima</i>	12
<i>Cause and Effect</i>	13
<i>Undesirable Effects and Critical Root Causes</i>	13
<i>Solution Deterioration</i>	14
<i>Physical vs. Policy Constraints</i>	14
<i>Ideas Are NOT Solutions</i>	14
The Five Focusing Steps of TOC	14
1. <i>Identify the System Constraint</i>	14
2. <i>Decide How to Exploit the Constraint</i>	14
3. <i>Subordinate Everything Else</i>	15
4. <i>Elevate the Constraint</i>	15
5. <i>Go Back to Step 1, but Beware of “Inertia”</i>	15

Throughput, Inventory, and Operating Expense	16
<i>Throughput (T)</i>	16
<i>Inventory/Investment (I)</i>	17
<i>Operating Expense (OE)</i>	17
<i>Which Is Most Important: T, I, or OE?</i>	17
<i>T, I, and OE: An Example</i>	18
<i>T, I, and OE in Not-for-Profit Organizations</i>	19
<i>Universal Measures of Value</i>	19
<i>Passive Inventory</i>	20
<i>Active Inventory (Investment)</i>	20
<i>Managing T Through Undesirable Effects</i>	20
The TOC Paradigm	21
<i>Applications and Tools</i>	21
<i>Drum-Buffer-Rope</i>	21
<i>Critical Chain Project Management</i>	21
<i>Replenishment and Distribution</i>	22
<i>Throughput Accounting</i>	22
<i>The Logical Thinking Process</i>	22
The Intermediate Objectives Map	22
The Current Reality Tree	23
The Evaporating Cloud: A Conflict Resolution Diagram	24
The Future Reality Tree	25
The Prerequisite Tree	25
The Transition Tree	27
The Categories of Legitimate Reservation	28
The Logical Tools as a Complete “Thinking Process”	29
Figure 1.19: The Six Logical Tools as an Integrated Thinking Process	30
Chapter 2 Categories of Legitimate Reservation	31
Definition	32
Purpose	32
Assumptions	33
How to Use This Chapter	34
Description of the Categories of Legitimate Reservation	34
1. <i>Clarity</i>	34
Why Clarity Comes First	34
What Clarity Means	34
2. <i>Entity Existence</i>	36
Completeness	36
Structure	36
Validity	38
3. <i>Causality Existence</i>	38
4. <i>Cause Insufficiency</i>	40
The Ellipse	40
Relative Magnitude of Dependent Causes	42
How Many Arrows?	42
The Concept of “Oxygen”	42
5. <i>Additional Cause</i>	44
Magnitude	44
Test	44
A Unique Variation of Additional Cause	44

Complex Causality	46
<i>What Is It?</i>	46
<i>Cause Sufficiency</i>	46
Conceptual “AND”	46
<i>Additional Cause</i>	46
Magnitudinal “AND”	47
Exclusive “OR”	47
Symbols	48
6. <i>Cause-Effect Reversal</i>	49
The “Fishing Is Good” Example	49
The Statistical Example	49
The Medical Example	49
Test	50
7. <i>Predicted Effect Existence</i>	50
Conflict or Differences in Magnitude?	51
Tangible or Intangible?	52
Verbalizing Predicted Effect Existence	54
8. <i>Tautology (Circular Logic)</i>	55
Baseball Example	56
Vampire Example	56
Test	56
Using the CLR in a Group	57
<i>CLR Known by All</i>	58
<i>CLR Known Only by the Tree-Builder</i>	58
Sufficiency-Based vs. Necessity-Based Logic Trees	59
Symbols and Logic Tree Conventions	59
<i>Three Reasons to Standardize</i>	59
Credibility	60
Ergonomics	60
Miscommunication of Logic	60
<i>A Standard Symbol Set</i>	61
<i>A Standard Convention for Logical Connections</i>	62
Summary	64
Figure 2.36: Categories of Legitimate Reservation: Self-Scrutiny Checklist	65
Chapter 3 Intermediate Objectives Map	67
Introduction	68
Definition	68
Purpose	68
Assumptions	68
How to Use This Chapter	69
System Boundaries, Span of Control, and Sphere of Influence	69
<i>Span of Control</i>	70
<i>Sphere of Influence</i>	70
<i>The External Environment</i>	70
<i>Control vs. Influence</i>	70
Doing the Right Things vs. Doing Things Right	70
<i>The Goal</i>	70
<i>Who Sets the Goal?</i>	71
<i>Critical Success Factors and Necessary Conditions</i>	72

Description of the Intermediate Objectives (IO) Map	72
<i>Strategic Application</i>	73
<i>A Hierarchy of Systems</i>	73
<i>IO Maps Are Unique</i>	74
<i>Characteristics of the IO Map</i>	75
<i>Examples of Strategic Intermediate Objectives Maps</i>	76
Process-Level IO Map	76
System-Level IO Map	76
How to Construct an Intermediate Objectives (IO) Map	76
1. <i>Define the System</i>	76
2. <i>Determine the System Goal</i>	78
3. <i>Determine the Critical Success Factors</i>	79
4. <i>Determine the Key Necessary Conditions</i>	80
5. <i>Arrange the IO Map Components</i>	82
6. <i>Connect the Goal, Critical Success Factors, and Necessary Conditions</i>	82
7. <i>Verify the Connections</i>	83
The “10,000-Foot Test”	85
8. <i>Enlist Outside Scrutiny of the Entire IO Map</i>	85
Figure 3.14: Procedures for Constructing an Intermediate Objectives (IO) Map – abbreviated checklist	86
Summary and Conclusion	87
Figure 3.15: Example: A Real-World IO Map	88

PART II – GAP ANALYSIS AND CORRECTION **89**

Chapter 4 Current Reality Tree	91
Definition	92
Purpose	93
Assumptions	94
How to Use This Chapter	94
Description of the Current Reality Tree (CRT)	95
<i>A Single Tool or Part of a Set</i>	96
<i>Span of Control and Sphere of Influence</i>	97
<i>Correlation vs. Cause and Effect</i>	98
Predicting Rain in Siberia: A Simple Example of Correlation	98
Fibromyalgia and Myofascial Pain: A Complex Real-World Example	99
<i>Undesirable Effects</i>	100
Undesirable by What Standard?	100
How to Identify and Check for Undesirability	101
Existence in Reality	101
Why the Emphasis on UDEs?	102
<i>Root Causes</i>	102
<i>Core Problems and Root Causes</i>	105
The “70 Percent” Criterion	105
Inability to Act on a Core Problem	105
A Solution to the Core Problem Conundrum	106
<i>Critical Root Cause: A Definition</i>	108
<i>Main Body of the CRT</i>	108
<i>Archetypical CRTs</i>	109
<i>Depicting a Current Reality Tree</i>	109
Entities	109

Entities in a Current Reality Tree	110
Arrows	110
Underlying Assumptions	111
Ellipses, Magnitudinal ANDs, and Exclusive ORs	112
<i>Ellipses</i>	112
<i>Magnitudinal ANDs</i>	113
<i>Exclusive ORs</i>	114
Variations on a Theme	115
Numbering Entities in a Tree	115
The Most Common Logical Errors in a Sufficiency Tree	118
<i>Clarity in the Arrow</i>	118
Don't Induce Confusion	119
Don't Miss Opportunities to Break the Chain of Cause and Effect . . .	119
<i>Cause Insufficiency</i>	120
The Concept of "Oxygen" Revisited	121
<i>Entity Existence</i>	122
Reading a Current Reality Tree	122
Negative Reinforcing Loops	124
<i>Reading a Negative Reinforcing Loop</i>	125
How to Construct a Current Reality Tree	126
<i>Gather Materials</i>	127
1. <i>Define the System to be Modeled</i>	128
2. <i>Determine the Undesirable Effects</i>	128
Compare Reality with Benchmarks of System Success	129
Create a Starting Matrix	129
3. <i>Determine the First Two Levels of Causality</i>	130
Transfer UDEs and Causes to Post-it Notes	130
4. <i>Begin the Current Reality Tree</i>	131
5. <i>Improve the Logic of the Initial Clusters</i>	131
6. <i>Identify Possible Additional Causes</i>	133
Two Criteria for Additional Causes	134
7. <i>Look for Lateral Connections</i>	135
8. <i>Build the Cause-and-Effect Chains Downward</i>	136
9. <i>Scrutinize the Entire Current Reality Tree</i>	137
10. <i>Decide Which Root Causes to Attack</i>	138
Scrutinizing the Current Reality Tree	140
<i>The Categories of Legitimate Reservation</i>	140
<i>Techniques for "Shortstopping" Logical Challenges</i>	140
<i>When "All" or "None" Are Not Acceptable</i>	141
Inclusive and Exclusive	141
Qualifying Words	141
Too Many Arrows?	142
<i>Simple Logical Aid #1: Means, Method, and Motivation</i>	143
<i>Simple Logical Aid #2: The Syllogism</i>	144
Using the CRT with Other Parts of the Thinking Process	146
<i>The Current Reality Tree and the Evaporating Cloud</i>	146
<i>The Current Reality Tree and the Future Reality Tree</i>	146
Summary	147
Figure 4.45: Procedures for Constructing a Current Reality Tree (CRT) – abbreviated checklist	148
Figure 4.46: Current Reality Tree: Fordyce Corporation	152

Chapter 5	Evaporating Cloud	159
Definition		160
Purpose		161
Assumptions		161
How to Use This Chapter		162
Description of the Evaporating Cloud		162
<i>The Nature of Conflict</i>		163
<i>Conflict Is Not Always Obvious</i>		163
<i>Two Types of Conflict</i>		163
Opposite Conditions		163
Different Alternatives		163
<i>Compromise, “Win-Lose” or “Win-Win”?</i>		163
Compromise		164
Win-Lose		164
Win-Win		164
<i>An Indication of Hidden Conflict</i>		164
<i>“Breakthrough Solutions”</i>		164
<i>Elements of the Evaporating Cloud</i>		165
<i>Symbology</i>		165
Objective		166
Requirements		166
Prerequisites		168
<i>How the Evaporating Cloud Relates to the Current Reality Tree</i>		169
Why Do Root Causes of Undesirable Effects Exist?		171
Policies and Constraints		171
Policy Constraints: A Source of Conflict		171
Conflict is Usually Embedded in the CRT		172
<i>Assumptions</i>		172
Invalid Assumptions		172
Some Assumptions Can Be Invalidated		173
“Win-Win” vs. “Win-Lose”		175
Five Potential “Break” Points		175
Invalid Assumptions: An Example		176
<i>Injections: The Role of Invalid Assumptions</i>		177
How Are Injections Related to Assumptions?		178
Injections: Actions or Conditions?		180
“Silver Bullets”		180
<i>Creating “Breakthrough” Ideas to Resolve Conflict</i>		180
All Arrows Are Fair Game		181
Is the Idea Feasible?		182
<i>Reading an Evaporating Cloud</i>		182
Verbalizing Assumptions		182
What to Remember About Evaporating Clouds		183
How to Construct An Evaporating Cloud		184
<i>A Nine-Step Path to Conflict Resolution</i>		184
1. Construct a Blank Evaporating Cloud		185
2. Articulate the Conflicting “Wants” of Each Side		185
3. Determine the “Needs” of Each Side		186
The “Easy Way” to Articulate Requirements		187
4. Formulate the Objective		188
Why Use an Intermediate Objectives Map?		188

5. Evaluate the Whole Relationship	190
6. Develop Underlying Assumptions	192
Extreme Wording	192
7. Evaluate Assumptions	194
8. Create Injections	195
9. Select the Best Injection(s)	195
Scrutinizing An Evaporating Cloud	197
Reflection of Current Reality	197
Perception	198
Figure 5.32: Procedures for Constructing an Evaporating Cloud – abbreviated checklist	199
Figure 5.33: Evaporating Cloud: Master Blank Form	202
Figure 5.34: Evaporating Cloud: Wurtzburg Corporation	203
Summary	204
Chapter 6 Future Reality Tree	205
Definition	206
Purpose	207
Assumptions	208
How to Use This Chapter	208
Description of the Future Reality Tree	209
<i>A Real-World Example</i>	209
<i>A Framework for Change</i>	210
<i>Negative Branches</i>	211
<i>The Positive Reinforcing Loop</i>	211
<i>Future Reality Tree Symbology</i>	213
<i>Injections</i>	214
Injections: Actions or Conditions?	215
The Risk of Actions as Injections	216
<i>Build Upward, from Injections to Desired Effects</i>	216
Example: Building a House	217
<i>Multiple Injections: The “Silver Bullet” Fallacy</i>	217
<i>Where Injections Come From</i>	217
<i>The Future Reality Tree and Other Thinking Process Trees</i>	219
The Future Reality Tree and the Current Reality Tree	219
The Logical Structure of Reality, Current and Future	220
The Future Reality Tree and the Evaporating Cloud	221
The Future Reality Tree and the Prerequisite Tree	222
The Future Reality Tree as a “Safety Net”	225
<i>Negative Branches</i>	225
Using the Negative Branch as a “Stand-Alone”	225
Added Realities	226
Assumptions	228
“Trimming” Negative Branches	228
When to Raise Negative Branch Reservations	228
<i>Positive Reinforcing Loops</i>	228
<i>Strategic Planning with a Future Reality Tree</i>	230
How to Construct a Future Reality Tree	231
1. Gather Necessary Information and Materials	231
2. Formulate Desired Effects	232
Positive, Not Neutral	232

Use Present Tense	233
Lay Out Desired Effects	233
3. <i>Add the Injection(s) and Evaporating Cloud Requirements</i>	234
Where Do We Find Injections?	234
Injections at the Bottom	235
4. <i>Fill in the Gaps</i>	235
Build Upward	235
Continue Building from the Expected Effects	235
5. <i>Build in Positive Reinforcing Loops</i>	237
6. <i>Look for Negative Branches</i>	238
7. <i>Develop Negative Branches</i>	240
8. <i>Trim Negative Branches</i>	240
9. <i>Incorporate the “Branch-Trimming” Injection into the FRT</i>	241
10. <i>Scrutinize the Entire FRT</i>	241
Scrutinizing a Future Reality Tree	242
Existence Reservations	242
Additional Cause	242
Scrutinizing Injections	243
“Oxygen”	243
Summary	243
Figure 6.27: Procedures for Constructing a Future Reality Tree	244
Figure 6.28: Using the Negative Branch as a Stand-Alone Tool	248
Figure 6.29: Future Reality Tree Example: Fordyce Corporation	252
PART III – EXECUTING CHANGE	259
Chapter 7 Prerequisite and Transition Trees	261
A Consolidation of Two Trees	262
Definition	263
Purpose	264
Assumptions	264
How to Use This Chapter	265
Description of the Prerequisite Tree	265
<i>Necessity vs. Sufficiency</i>	265
<i>Depicting a Prerequisite Tree</i>	267
<i>The Objective</i>	267
<i>Intermediate Objectives</i>	268
Different Alternatives	270
Not Always a One-to-One Relationship	270
Obstacles	270
Overcome, Not Obliterate	271
Enlist Assistance to Identify Obstacles	272
<i>A Single Tool or Part of a Set</i>	272
<i>Intermediate Objectives: Actions or Conditions?</i>	272
<i>Obstacles: Always Conditions</i>	273
<i>Sequence Dependency</i>	274
<i>Parallelism</i>	274
<i>Reading a Prerequisite Tree</i>	276
Top to Bottom	277
Bottom to Top	278

Building a Prerequisite Tree	279
1. Determine the Objective	279
2. Identify All Intermediate Objectives	279
3. Surface All Possible Obstacles	281
4. Organize the Intermediate Objectives and Obstacles	281
5. Sequence the Intermediate Objectives Within Each Branch	284
6. Connect the Intermediate Objectives	285
7. Overcome the Obstacles	285
8. Integrate the Branches	287
9. Connect the Main Body of the Tree to the Objective	289
10. Scrutinize the Entire Tree	290
Scrutinizing a Prerequisite Tree	290
Entity Existence	291
Cause Sufficiency	291
Additional Cause	292
The IO-Obstacle Validity Test	292
The Transition Tree	294
A Little History	294
Prerequisite Tree and Transition Tree: Original Concept	295
Transition Tree Structure	297
The Five-Element Transition Tree	299
In Search of Robust Execution	300
Managing Change as a Project	300
Critical Chain Project Management	300
What Critical Chain Project Management Does	300
What Critical Chain Project Management Requires	301
A Three-Phase Change Management Framework	301
Summary	302
Figure 7.31: Procedures for Constructing a Prerequisite Tree	304
Figure 7.32: Prerequisite Tree Self-Scrutiny Checklist	307
Figure 7.33: Prerequisite Tree: Conference Planning and Management	308
Chapter 8 Changing the Status Quo	311
Purpose	312
Assumptions	312
How to Use This Chapter	313
The Key to System Improvement	313
The Elements of System Improvement	314
Reinforcement	315
Human Behavior	315
Active Resistance	315
Passive Resistance	316
Is Behavior Logical?	316
Changing Minds, or Changing Behavior?	316
Why Do People Resist Change?	317
Maslow	317
Herzberg	318
McClelland	318
Adams	318
Anaclitic Depression Blues	319
Security or Satisfaction?	320

<i>The Impact on Solutions</i>	320
Leadership	322
<i>Leadership Is About People</i>	322
<i>Leadership and the Blitzkrieg</i>	323
Mutual Trust	323
Personal Professional Skill	323
Moral Contract	324
Focus	324
<i>Level 5 Leadership</i>	325
Leadership and Behavior	325
<i>The Leader's Behavior</i>	327
<i>Subordinates' Behavior</i>	328
Creating and Sustaining Desired Behaviors	328
<i>Behavior Change is a Leadership Function</i>	329
<i>A Behavioral Approach to Change</i>	329
Rewards or Reinforcement?	330
A General Strategy for Implementing Change	331
<i>A Common Scenario</i>	331
Assumptions	331
How Change "Gets In"	323
<i>The Leader as Change Agent-in-Chief</i>	323
<i>A Model for Implementing Change</i>	333
1. Leader Commitment	335
2. Modified Behavior Defined	335
3. Mission/Task Charter Communicated	335
4. Leader Commitment Demonstrated	336
5. Subordinate Commitment	336
6. Performance Management Process	336
<i>A Last Thought about Ensuring Effective Change</i>	336
Summary	337
Epilogue	339
Appendices	
Appendix A: Strategic Intermediate Objectives Map	341
Appendix B: Executive Summary Trees	343
Appendix C: Current Reality Tree Exercise	356
Appendix D: Evaporating Cloud Exercise	357
Appendix E: The 3-UDE Cloud	359
Appendix F: The Challenger Conflict	369
Appendix G: Correlation Versus Cause and Effect	376
Appendix H: Theories of Motivation	377
Appendix I: Legal Application of the Thinking Process	382
Appendix J: Transformation Logic Tree Software	394
<i>Glossary of Thinking Process Terms</i>	397
<i>Bibliography</i>	401
<i>Index</i>	405

Preface

Books are snapshots in time. The previous edition of this book, *Goldratt's Theory of Constraints (GTOC)*, was a snapshot of “the state of the art” of the Thinking Process in 1996. But time passes, and people and things evolve. The Thinking Process is no exception.

Since 1996, I've applied the Thinking Process in commercial companies, government agencies, and not-for-profit organizations. And I've taught it to people throughout the United States, South America, Europe, Japan, Korea, and Australia. In each of these consulting and teaching engagements, *GTOC* was the basis of my work.

But over time I began to notice a developing tendency: I was diverging from the techniques and procedures I'd established in *GTOC*. In teaching, I found that I needed to modify the procedures for constructing the logic trees in order to overcome difficulties that some students had in learning to apply them. In my own applications, I found that the need to quickly develop more robust trees gradually drew me away from the procedures in the first edition.

This shouldn't be surprising. The Thinking Process was relatively new and still evolving when I wrote *GTOC*. Any new methodology can be improved. Yet *GTOC* still stood as a snapshot in time. In teaching Thinking Process courses, I began to supplement *GTOC* with a three-ring binder containing newer guidance and examples. By 2005, I had so transformed the way I taught the Thinking Process that *GTOC* became an adjunct to my courses, supporting the three-ring binder, rather than the other way around.

The transformation of the Thinking Process over the past ten years has been a good thing. In 1996, most people teaching the Thinking Process—including me—required ten days to cover it all. With some innovations, I found that I could include more material in six days than I originally could in ten, and still finish early. In 2006, I decided it was time to incorporate what I've learned about faster and better ways to teach and apply the Thinking Process into a new edition of *GTOC*.

But as I began to edit the original text of *GTOC*, I realized just how substantial the changes would be. It turned out to be far more than just an update of the 1996 version—it was a whole new approach to building and applying logic trees. For that reason alone, merely calling this book a second edition of *GTOC* would have been an inaccurate representation of the content, comparable to calling a 2006 Ford automobile “Model T, second edition.”

Moreover, while the Thinking Process has its roots in the Theory of Constraints, it has since realized a much broader applicability in system analysis and systems thinking. Much as some trademarked brand names (e.g., Kleenex, Google, Post-it Notes, Scotch tape, and so on) enjoy a kind of evolution to generic usage over time, so too has the Thinking Process as a methodology become more of a generic logical analysis process. So it's appropriate to title this book in a way that conveys the broader applicability of the method—to characterize it as what it is: *the Logical Thinking Process, a systems-level approach to policy analysis*. At the risk of hyperbole, I would go so far as to say it's the most powerful such methodology yet created.

None of this alters the fact that this marvelous logical method was created and introduced by Eliyahu M. Goldratt as a means of identifying and breaking policy constraints. Though the principles of deductive logic date back to the days of Aristotle, it took Goldratt to make them more than just a topic of curiosity and academic interest. The Thinking Process is probably the first widely-used, practical tool for the application of deductive logic, and its users should not forget that Goldratt made this possible.

A major contribution of real value that this book offers users of the Thinking Process is software. Anyone who has used the Thinking Process for long knows what a challenge this is. When Goldratt first introduced the Thinking Process, computer-based graphics programs capable of rendering the logic trees were few, far between, and expensive. For the first several years, the only way to build and present Thinking Process trees involved using Post-it Notes connected by hand-drawn lines on flip-chart paper taped to walls. In the mid-1990s, a variety of drawing and flowcharting programs became available for both Macintosh computers and IBM PCs, but they were relatively expensive and they didn't lend themselves directly to Thinking Process applications. Icons needed to be created or modified, and standardization of symbols was consequently almost nonexistent.

In 2006, I was privileged to meet Dr. Mark Van Oyen, a professor of engineering at the University of Michigan, who had begun development of a unique graphical software application—one that was designed primarily to create Thinking Process logic trees, and only secondarily for other flowcharting uses. Dr. Van Oyen and I came to a meeting of the minds on incorporating that software, *Transformation Logic Tree*, with this book. The compact disk provided here contains a full-function, unrestricted copy of version 1.0 for new and experienced users of the Thinking Process alike to use in building their logic trees. Appendix J includes more information on how to install and use the software.

This book contains new examples of logic trees from a variety of real-world applications. Most of the diagrams and illustrations are new and improved. Explanations and procedures for constructing the logic trees are considerably simplified.

Yet notwithstanding all these improvements, the Thinking Process still requires concerted effort to learn and apply well. A book like this can't be all things to all people. Simply reading a book won't make you an expert in the Thinking Process. Only regular, repetitive practice can do that. And specialized training from someone who thoroughly understands (and has effective teaching skills) is advisable in order to realize maximum benefit. These can also compress the learning curve from months to days.

Even so, you're still likely to have questions that this book doesn't adequately address. I encourage readers to contact me directly with any such questions, as well as with comments, pro or con, about the book. How else can things improve?

H. William Dettmer

Acknowledgments

Any book such as this is the culmination of effort by more people than just the author alone. I would be remiss if I failed to recognize those dedicated, consummate professionals who have helped me in a variety of ways to create the book you're reading now.

This help starts with ten years of feedback from Thinking Process students and practitioners who are too numerous to name—and I'd undoubtedly slight some by forgetting to mention them if I tried. For the review of parts or all of the manuscript of this book, I'm indebted to (in reverse alphabetical order), Christopher Zephro, Haruyuki Uchiyama, Christoph Steindel, Paul Selden, Timothy Sellan, Chet Richards, Wayne Patterson, Sadashiv Pandit, Dieter Legat, Larry Leach, David Hodes, and Jerry Harvey.

I am also indebted to Stephen F. Kaufman, hanshi 10th dan, who graciously shared with me his understanding of the Way of the Warrior as expressed in the writings and life of Miyamoto Musashi, the prototypical samurai.

The high-quality production of this book would not have been possible without the initiating efforts of Matt Meinholz and Paul O'Mara at Quality Press; Janet Sorensen, who created this layout and superbly rendered my initial drawings into the crisp, clean illustrations you find here; and Linda Presto, whose eagle-eye copyediting and superlative skill in constructing the indispensable, invaluable index helped deliver the truly professional result you hold in your hand.

Mark Van Oyen earns my deep appreciation for contributing the *Transformation Logic Tree* software to the efforts of aspiring Thinking Process practitioners, and for his willingness to see it included with this book.

Finally, none of us would have the Thinking Process at all if not for the creativity of Eli Goldratt.

Introduction

What's really new in this book that warrants a change in the title? First, I've learned how to streamline the process of constructing the logic trees while simultaneously ensuring that the results are more logically sound and closer representations of reality than ever before. Whereas Current Reality Trees (CRT) once took several days to complete, a better-quality tree is now possible in a matter of several hours. When used as part of an integrated Thinking Process, all of the trees are now more precisely and seamlessly aligned with one another.

This better integration is possible because of a new application of an old (and little used) tree: the Intermediate Objectives (IO) Map. An hour or less spent perfecting an IO Map at the beginning shaves days off completion of the rest of the process, and the results are much more robust. So, with this book, the IO Map takes its place as the first step in the Thinking Process.

A second major change is in the relationship between the Evaporating Cloud and the Current Reality Tree. As Goldratt originally conceived the Thinking Process, these two trees enjoyed a close logical relationship, but it was frequently a difficult transition. Sometime in the late 1990s, a number of Thinking Process practitioners began using an approach to analyzing problems called "the 3-UDE Cloud."* The 3-UDE Cloud was then used to create something called a "communication current reality tree." This combination of the Evaporating Cloud and the Current Reality Tree certainly streamlined the process of creating these two trees in many situations, but this process is logically flawed (and often myopic). I found the results of this process to be incomplete, too narrowly focused, and not really representative of a system's larger issues. It certainly did offer some efficiencies and economies over the Thinking Process as originally described in *GTOC*—though at the expense of logical quality and robustness. This book explains the deficiencies of the "3-UDE Cloud to communication CRT" approach in Appendix E. Chapter 5 explains an easier, more logically sound way to integrate the Current Reality Tree with the Evaporating Cloud.

A third major change is a reorientation of solution implementation. In the original incarnation of the Thinking Process, injections (ideas for solutions) from the Future Reality Tree went through two subsequent steps: a Prerequisite Tree to help identify and overcome obstacles, and a Transition Tree to "flesh out" the step-by-step implementation plan. One of the phenomena I noticed over the past decade was the tendency for students

* UDE is an acronym for undesirable effect.

learning the Thinking Process to incorporate much more detail into the Prerequisite Tree than it was originally intended to have. And at the same time, there was less patience with the often mind-numbing detail of the Transition Tree.

As an experiment in one Thinking Process course, I suggested that students dispense with the Transition Tree altogether and instead incorporate more detail into their Prerequisite Trees. Not only did implementations become faster and easier, but there was no deterioration in their quality. And everyone preferred this approach because of its speed. Because almost without exception the people I work with are competent professionals, it's no problem for them to execute change from comprehensive Prerequisite Trees alone. The Transition Tree became superfluous.

Yet there was still an opportunity to realize some synergy among tools in change execution. The Theory of Constraints offers the best improvement to project scheduling and management methods conceived in the past 50 years: critical chain. Since the new Prerequisite Tree identifies all the activities needed to execute a change as intermediate objectives, it's a natural next step to use it to create a project activity network. These activities can be implemented using Critical Chain Project Management. So, this version of the Thinking Process "retires" the Transition Tree in favor of the marriage of a more detailed Prerequisite Tree and Critical Chain Project Management.

There's another "elephant in the parlor" that attends any system improvement methodology, including (but not limited to) the Thinking Process: *change management*. The challenge of changing existing ways of doing things, which is really what the Thinking Process is designed to facilitate, goes far beyond logic. It's necessary, but not sufficient, to create technically and economically sound solutions to problems. But even so, some estimates of failure run as high as 80 percent. There's a reason why many major systemic changes fail to realize expectations fully, or fail outright. The missing sufficiency is the failure of most methods, including the Thinking Process, to inherently address the psychology of change. Theory of Constraints philosophy has touched on this challenge before, but only in a superficial way (that is, the so-called layers of resistance). Most methods, such as Six Sigma and lean, don't address it at all.

Yet with potentially valuable solutions falling by the wayside because system improvers fail to consider the psychology of change, it's somewhat surprising that more methods don't aggressively deal with this problem. I've tried to start that process in Chapter 8, "Changing the Status Quo." But it's only a start. The psychology of change is a field unto itself. All I can do in this book is to point you in the right direction and provide a "push start."

There are two components to this push. The first is the concept of the executive summary tree, a tool for reducing complete, complex Thinking Process analysis to a streamlined version that can be presented succinctly to an executive in a limited period of time, without compromising the logical soundness of the analysis. The second is a six-stage model for handling the psychology of change. Executive summary trees are described in detail in Appendix B. The behavioral change model is introduced in Chapter 8.

This book is organized to take you from the general to the specific, following a tried-and-true scientific systems analysis approach developed at the Rand Corporation in the 1950s by E. S. Quade. The approach begins with a determination of the desired system outcome, defines the problem, creates alternatives, tests those alternatives, and determines the best alternative according to a predetermined decision rule. However, the traditional systems analysis approach stops short of implementation. This book goes the extra mile. It's divided into three major parts.

Part I, "The Destination," sets the stage, the ground rules, and the expected outcome. In Chapter 1, we start with an overview of systems thinking and constraint management in particular, including the principles of constraint theory and its major tools. Chapter 2

begins our more detailed examination of the Thinking Process with an explanation of the Categories of Legitimate Reservation—the logical “rules of the game.” After all, we can’t excel at the game if we don’t know the rules.

Chapter 3 starts our comprehensive exploration of the Thinking Process itself. Following Quade’s scientific systems analysis approach, we learn how the Intermediate Objectives Map is used to establish the standard for desired performance of our system: the goal, critical success factors, and supporting necessary conditions.

Part II, “Gap Analysis and Correction,” defines the magnitude of the divide between the existing system and the aforementioned expected outcome. In Chapter 4, we learn how to construct a Current Reality Tree to express the gap as undesirable effects (UDEs) and logically trace the path back to critical root causes for these UDEs. Chapter 5 describes the resolution of conflict associated with changing the critical root causes, and Chapter 6 lays out proposed solutions for logical testing and “bulletproofing” (consideration of the law of unintended consequences).

Part III, “Executing Change,” addresses the implementation of the new direction that was logically tested in Chapter 6. Construction of the Prerequisite Tree, Chapter 7, provides the framework of an execution plan and shows how Critical Chain Project Management can help with the technical aspects of implementation. However, as Will Rogers once observed, “Plans get you into things, but you’ve got to work your own way out.” Chapter 8 emphasizes the importance of a concerted effort to accommodate the human element in change. The Thinking Process may be necessary, but it’s not sufficient alone. And while Chapter 8 can’t provide more than a survey of change management techniques, it does offer an introduction to some human-oriented aids to consider.

Finally, nine appendices provide real-world examples, exercises, and deeper insight into the Logical Thinking Process. And the tenth appendix introduces the *Transformation Logic Tree* software included with this book.

It’s difficult for any book to be all things to all people. This one is as comprehensive as I can make it. It can supplement formal training, facilitate self-study, and be a continuing desk reference. Or it can be a dandy doorstop. Which it will be for you is for you alone to determine.

Without the assistance of a teacher many roads become open to a practitioner, some on the correct path and some on the incorrect path. It is not for everyone to be without guidance—only a few, and they are exceptional, can make a journey to wisdom without a teacher. You must have extraordinary passion, patience, and self-discipline to make a journey alone. The goals must be understood, and no diversion can be acknowledged or permitted if you are to attain enlightenment within the sphere of a chosen art. This is a very difficult road to travel and not many are made for it. It is frustrating, confusing, very lonely, certainly frightening, and it will sometimes make you think you do not have much sanity left to deal with the everyday surroundings of your world. Also, there is no guarantee that you will attain perfection. It must all come from inside you without any preconceived notions on your part.

And so we begin...

Introduction to the Theory of Constraints

Profound knowledge must come from outside the system, and by invitation.

—W. Edwards Deming

SYSTEMS AND “PROFOUND KNOWLEDGE”

W. Edwards Deming maintained that real quality improvement isn’t possible without profound knowledge.^{7:94-98} According to Deming, profound knowledge comes from:

- An understanding of the theory of knowledge
- Knowledge of variation
- An understanding of psychology
- Appreciation for systems

“Appreciation for systems”—what does that mean? A system might be generally defined as a collection of interrelated, interdependent components or processes that act in concert to turn inputs into some kind of outputs in pursuit of some goal (see Figure 1.1). Systems influence—and are influenced by—their external environment. Obviously, quality (or lack of it) doesn’t exist in a vacuum. It can only be considered in the context of the system in which it resides. So, to follow Deming’s line of reasoning, it’s not possible to improve quality without a thorough understanding of how that system works. Moreover, the Logical Thinking Process that is the subject of this book also provides a solid foundation of understanding of the theory of knowledge: how we know what we know.

Figure 1.1 A basic system and its environment.

THE SYSTEM'S GOAL

Let's look at systems from a broader perspective. Why do systems exist? In the most basic sense, the answer is, "To achieve a goal." If a system's purpose is to achieve some goal, who gets to decide what that goal should be? Obviously, in natural systems the answer to this question is often beyond the scope of human understanding. But in human organizational systems, which are the primary focus of this book, the goal setter ought to be the system's owner—or owners. If you or I paid for the system, we'd expect to be the one to decide what that system's goal should be. Privately held companies respond to the directions of their owners. Publicly held corporations work toward the goals of their stockholders—or at least they're supposed to. Government agencies are essentially "owned" by the taxpayers and should be doing what the taxpayers expect them to do.

The essence of management is recognizing the need for change, then initiating, controlling, and directing it, and solving the problems along the way. If it were not so, managers wouldn't be needed—only babysitters.

THE MANAGER'S ROLE

In most complex systems, the responsibility for satisfying the owners' goals rests with the managers of the system—from the chief executive officer down to the frontline supervisor. In a general sense, the Theory of Constraints (TOC) is about management.

1. *Anyone can make a decision, given enough facts.*
2. *A good manager can make a decision without enough facts.*
3. *A perfect manager can operate in perfect ignorance.*

—Spencer's Laws of Data

Who Is a Manager?

Inevitably, some readers will respond, "But I'm not a manager. Why would the Theory of Constraints be important to me?" The truth is, we're all managers. Everyone is a manager of something—in different arenas, perhaps, but a manager nonetheless. Whether you're in charge of a large corporation, a department, or a small team, you're a manager. Even if you're "none of the above," you're still a manager. Under ideal circumstances, all individuals manage their lives and careers, though sometimes they don't do a very effective job of it.

Some of us have more than one management role. Basically, we differ only in our span of control and the size of our sphere of influence. At the very least you manage (or possibly fail to manage) your personal activities, your time, and perhaps your finances. For example, a homemaker manages a household; a lawyer manages legal case preparation and litigation; a student manages time and effort.

One of the hallmarks of effective managers is that they deal less with the present and more with the future. In other words, they concentrate on "fire prevention" rather than "fire fighting." If you're more focused on the present than the future, you'll always be in a time lag, chasing changes in your environment—a reactive rather than a proactive mode.

*Have you seen them? Which way did they go? I must be after them,
for I am their leader!*

What Is the Goal?

The Theory of Constraints rests on the admittedly somewhat rash assumption that managers and/or organizations know what their real purpose is, what goal they're trying to achieve. Unfortunately, this isn't always the case. No manager can hope to succeed without knowing four things:

- What the ultimate goal is
- What the critical success factors are in reaching that goal
- Where he or she currently stands in relation to that goal
- The magnitude and direction of the change needed to move from the status quo to where he or she wants to be (the goal)

This might be considered "management by vector analysis." But in fact that's really what managers do: They determine the difference between what is and what should be, and they change things to eliminate that deviation.

Average managers are concerned with methods, opinions, and precedents. Good managers are concerned with solving problems.

—Unknown

Goal, Critical Success Factor, or Necessary Condition?

If you're a manager, how do you know what the system's goal is? Frequently a system's managers—and perhaps even the owners—have different ideas about the system's goal. In a commercial enterprise, the stockholders (owners) usually consider the system's goal to be "to make more money." The underlying assumption here is that a system making money pays dividends to stockholders who, in turn, make more money.

The managers in a system might see the goal a little differently. While they acknowledge the need to make money for the stockholders, they also realize that other things are important—things like competitive advantage; market share; customer satisfaction; a satisfied, secure workforce; or first-time quality of product or service. Factors like these often show up as goals in strategic or operating plans. But are they really goals or are they necessary conditions?

For the purposes of this book, a goal is defined as *the result or achievement toward which effort is directed*.¹⁹ But in complex systems we normally can't jump directly to desired outcomes without satisfying some necessary conditions. A necessary condition is *a circumstance indispensable to some result, or that upon which everything is contingent*.¹⁸ Inherent in these definitions is a *prerequisite relationship*: you must satisfy the necessary conditions in order to attain the goal.

How many necessary conditions does it take to realize a goal? The answer is, "It depends"—on how detailed you want to be. Stephen Covey recommends beginning "with the end in mind."^{4:95} That's obviously the goal itself, as we've defined it.

But if we conceive of the process of goal attainment as a journey rather than a destination, there are clearly some intermediate progress milestones along the way—some "show-stoppers" without which we won't be able to reach the goal. Normally there aren't too many of these. I submit that there are no more than three to five, and perhaps fewer than three.

We could call these *critical success factors* (CSF). They are definitely necessary conditions for goal attainment, but because they're major milestones, there won't be very many. Most of what people might consider necessary conditions actually support (are required to satisfy) these critical success factors. As we'll see in Chapter 3, "The Intermediate Objectives Map," the goal, critical success factors, and subordinate necessary conditions can be configured as a hierarchy.

Goldratt suggested that the relationship is actually interdependent, at least at the goal-CSF level. In other words, if the system's owner decides to change the goal—say, to one of the critical success factors—the original goal can't be ignored. But it will most likely revert to the CSF position vacated by the new goal. Because of this interdependency, the goal is really no more than one of the system's "constellation" of critical success factors that has been arbitrarily designated for primacy.

For example, your stockholders (represented by the board of directors) might decide that "increased profitability" is the company's goal (see Figure 1.2). In this case, "customer satisfaction," "technology leadership," "competitive advantage," and "improved market share" might all be necessary conditions that you can't ignore without the risk of not attaining the profitability goal. But you might just as easily consider the goal to be "customer satisfaction," as many quality-oriented companies do these days. In this instance, "profitability" becomes a necessary condition without which you can't satisfy customers. Why? Because unprofitable companies don't stay in business very long, and if they're not in business, they can't very well satisfy customers.

The major difference between rats and people is that rats learn from experience.

—B. F. Skinner

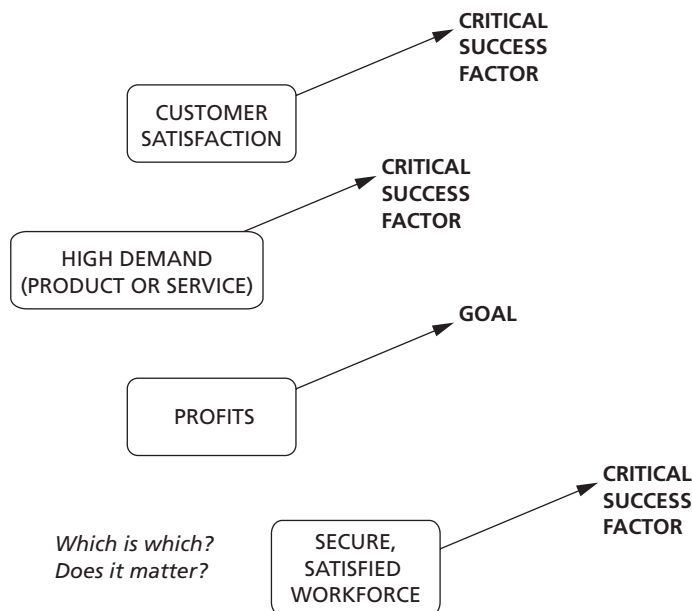

Figure 1.2 Goal or critical success factor?

THE CONCEPT OF SYSTEM CONSTRAINTS

Let's assume for the moment that you, the manager, have decided what your system's goal is and what the CSF and necessary conditions are for attaining it. Are you attaining that goal right now? Most people would agree that they could be doing a better job of progressing toward it.

What keeps your system from doing better? Would it be fair to say that something is constraining your system—keeping it from realizing its maximum potential? If so, what do you think that constraining factor might be? The chances are that everybody in your organization has an opinion about it. But who's right? And how would you know if they're right? If you can successfully answer that question, you probably have a bright future ahead of you. Let's see if we can help you find that answer. To do this, we'll go back to the concept of a system.

Systems as Chains

Goldratt likens systems to chains, or to networks of chains. Let's consider the chain in Figure 1.3 a simple system. Its goal is to transmit force from one end to the other. If you accept the idea that all systems are constrained in some way, how many constraints do you think this chain has?

The "Weakest Link"

Let's say you keep increasing the force you apply to this chain. Can you do this indefinitely? Of course not. If you do, eventually the chain will break. But where will it break—at what point? The chain will fail at its weakest link (see Figure 1.3). How many "weakest links" does a chain like this have? One—only one. There may be another link or two that are very close in "weakness," but there is only one weakest link. The chain will fail first at only one point, and that weakest link is the constraint that prevents the chain (system) from doing any better at achieving its goal (transmission of force).

Figure 1.3 A system: the "chain" concept.

Constraints and Non-constraints

So we can conclude that our chain has only one link constraining its current performance. How many non-constraints does it have? An indeterminate number, but equal to the number of remaining links in the chain. Goldratt contended that there is usually only one constraint in a system at any given time. Like the narrow neck of an hourglass, that one constraint limits the output of the entire system. Everything else in the system, at that exact time, is a non-constraint.

Let's say we want to strengthen this chain (improve the system). Where would be the most logical place to focus our efforts? Right—the weakest link. Would it do us any good to strengthen anything except the weakest link (that is, a non-constraint)? Of course not. The chain would still break at the weakest link, no matter how strong we made the others. In other words, efforts on non-constraints—nearly all of a system—will *not* produce immediate, measurable improvement in system capability.

Now let's assume we're smart enough to figure out which link is the weakest, and let's say we double its strength. It's not the weakest link anymore. What has happened to the chain? It has become stronger, but is it twice as strong? No. Some other link is now the weakest, and the chain's capability is now limited by the strength of that link. It's stronger than it was, but still not as strong as it could be. The system is still constrained, but the constraint has migrated to a different component.

A Production Example

Here's a different look at the chain concept (see Figure 1.4). This is a simple production system that takes raw materials, runs them through five component processes, and turns them into finished products. Each process constitutes a link in the production chain. The system's goal is to make as much money as possible from the sale of its products. Each of the component processes has a daily capacity as indicated. The market demand is 15 units per day.

Where is the constraint in this chain, and why? The answer is Step C, because it can never produce more than six units per day, no matter how many the rest of the components produce. Where are the non-constraints? Everywhere else.

What happens if we improve the C process so that its daily capacity is now tripled, to 18 units per day? What constrains the system now, and why? The answer is Step D, because it can produce only eight units per day. Where are the non-constraints? Everywhere else.

- What is the maximum system output per day?
- Where is the weakest link? Why?

Figure 1.4 A production example.

Let's continue this improvement process, until Steps D, E, and A are all much better than before. Look at this new version of the production diagram (see Figure 1.5).

Where's the system's constraint now? It's in the marketplace, which is only accepting 15 units per day. We've finally removed the constraint, haven't we? Well, not really. All we've done is eliminate internal constraints. That which keeps our system from doing better in relation to its goal is now outside the system, but it's a constraint nonetheless. If we're going to attack this constraint, however, we'll need a different set of task skills and knowledge.

RELATION OF CONSTRAINTS TO QUALITY IMPROVEMENT

Deming developed 14 points that he offered as a kind of "road map to quality."⁵ Most other approaches to continuous improvement have comparable prescriptions for success. Deming's 14th point is, "Take action to accomplish the transformation." He amplifies this by urging organizations to get everyone involved, train everybody in the new philosophy, convert a "critical mass" of people, and form process improvement teams.^{6:86-92}

Management in most organizations interprets this point quite literally: Get everyone involved. Employee involvement is a very important element of Deming's theory, and of most other total quality philosophies, and for good reason: Success is inherently a cooperative effort. Most organizations having formal improvement efforts include employees, in the process usually in teams.

Let's assume that these improvement teams are working on things that "everybody knows" need improving. If we accept Goldratt's contentions about constraints and non-constraints, how many of these team efforts are likely to be working on non-constraints? Answer: probably all but one (see Figure 1.6). How many of us know for sure exactly where in our organizations the constraint lies? If our management isn't thinking in terms of system constraints, yet they're putting everybody to work on the transformation, how much effort do you think might actually be unproductive?

"Wait a minute," you're probably thinking. "Continuous improvement is a long-term process; it can take years to produce results. We have to be patient and persevere. We'll need all of these improvements someday."

That's true. The way most organizations approach it, continuous improvement is a long-term process that may take years to show results. Limited time, energy, and resources are spread across the entire system, instead of focused on the one part of it that has the potential to produce immediate system improvement: the constraint. Impatience, lack of perseverance, and failure to see progress quickly enough are all reasons why many organizations give up on methods such as TQM and Six Sigma. People—including managers—soon get

- Now what's the maximum system output per day?
- Now where's the weakest link? Why?

Figure 1.5 Another version of the production example.

Figure 1.6 Who is working on a non-constraint?

discouraged when they see no tangible system results from the dedicated efforts they’ve put into process improvement. So interest, motivation, and eventually commitment to continuous improvement die from a lack of *intrinsic reinforcement*. Everybody might be working diligently, but only a few have the potential to really make a difference quickly. For most organizations, the real question is: Will our business environment allow us the luxury of time? Can we wait for the long term to see results?

Does it have to be this way? No. Goldratt developed the approach to continuous improvement called the Theory of Constraints. He even wrote a book describing this theory, called *The Goal*.¹¹ Another, entitled *It’s Not Luck*,¹⁰ demonstrates how the logical tools of the theory might be applied. The Theory of Constraints (TOC) is a prescriptive theory, which means it tells you not only what’s holding your system back, but also what to do about it and how to do it. A lot of theories answer the first question—what’s wrong. Some even tell you what to do about it, but those that do usually focus on processes rather than the system as a whole. And they’re completely oblivious to the concept of system constraints.

There is no such thing as staying the same. You are either striving to make yourself better or allowing yourself to get worse.

—Unknown

CHANGE AND THE THEORY OF CONSTRAINTS

Deming talks about “transformation,” which is another way of saying “change.” Goldratt’s Theory of Constraints is essentially about change. Applying its principles and tools answers the four basic questions about change that every manager needs to know:

- What’s the desired standard of performance?
- What must be changed? (Where is the constraint?)
- What is the appropriate change? (What should we do with the constraint?)
- How is the change best accomplished? (How do we implement the change?)

Remember that these are system-level questions, not process-level. The answers to these questions undoubtedly have an impact on individual processes, but they’re designed to focus efforts in system improvement. Processes are important, but our organizations ultimately succeed or fail as complete systems. What a shame it would be to win the battle on the process level, only to lose the war at the system level!

Why is the distinction between system and process so important? The answer lies in one of the fundamental assumptions of systems theory: the whole is *not* equal to the sum of its parts. The assumption that it is originates in a basic algebraic axiom. Unfortunately, however, complex systems are anything but mathematically precise. The improper allocation of this algebraic axiom to the management of organizations would sound like this:

If we break down our system into its components, maximize the efficiency of each one, then reassemble the components, we'll have the most efficient whole system.

It's been said that elegant theories are often slain by ugly, inconvenient facts. That's the case here. The mathematical, or analytical, approach to system improvement is one of those victims. It's also been said that "the devil is in the details." Where complex systems are concerned, those details make up many of the aforementioned ugly, inconvenient facts. And they are often in the *linkages* between system components, not in the components (links) themselves. Yet organizations continue to blithely polish the efficiency of these links, blissfully ignorant of the real location of the most vexing contributors to less-than-desirable system performance: the interfaces among components.^{3,3-4}

Most continuous improvement (CI) methods never adequately address how best to channel improvement efforts for maximum immediate effect. In other words, by using TOC in addition to CI methods such as Six Sigma, the problem of taking a long time to show results goes away. Effectively applying TOC in concert with CI, you're likely to find that CI and significant short-term results need not be mutually exclusive. So don't think about throwing away your CI toolbox. If anything, the traditional CI tools become more productive than ever, because TOC can suggest when and how to employ each one to best effect: on the current (and sometime future) system constraint.

It is not necessary to change; survival is not mandatory.

—W. Edwards Deming

TOC PRINCIPLES

Theories are usually classified as either descriptive or prescriptive. Descriptive theories, such as the law of gravity, tell us why things happen, but they don't help us to do anything about them. Prescriptive theories both explain why and offer guidance on what to do. TOC is a prescriptive theory, but we'll look at the descriptive part first.

Several principles converge to make the environment particularly fertile ground for the prescriptive part of Goldratt's theory. The accompanying chart (see Figure 1.7) lists most of these principles, but a few of them are worth emphasizing because of their striking impact on reality.

Systems as Chains

This is crucial to TOC. If systems function as chains, weakest links can be found and strengthened.

Local vs. System Optima

Because of the interdependence of system components and the effects of entropy, the optimum performance of the entire system is not equivalent to the sum of all the

- Systems thinking is preferable to analytical thinking in managing change and solving problems.
- An optimal solution deteriorates over time as the system's environment changes. A process of ongoing improvement is required to update and maintain the effectiveness of a solution—or replace it if it becomes irrelevant.
- If a system is performing as well as it can, not more than one of its component parts will be performing as well as they can. If all parts are performing as well as they can, the system as a whole will not be. The system optimum is not the sum of the local optima.
- Systems are analogous to chains. Each system has a “weakest link” (constraint) that ultimately limits the success of the entire system.
- Strengthening any link in a chain other than the weakest one does nothing to improve the performance of the whole chain.
- Knowing what to change requires a thorough understanding of the system's current reality, its goal, and the magnitude and direction of the difference between the two.
- Most of the undesirable effects within a system are caused by a few critical root causes.
- Root causes are almost never superficially apparent. They manifest themselves through a number of undesirable effects (UDEs) linked by a network of cause and effect.
- Elimination of individual UDEs gives a false sense of security while ignoring the underlying critical root causes. Solutions that do this are likely to be short-lived. Eliminating a critical root cause simultaneously eliminates all resulting UDEs.
- Root causes are often perpetuated by a hidden or underlying conflict. Eliminating root causes requires challenging the assumptions underlying the conflict and invalidating at least one.
- System constraints can either be physical or policy. Physical constraints are relatively easy to identify and simple to eliminate. Policy constraints are usually more difficult to identify and eliminate, but removing them normally results in a larger degree of system improvement than elimination of a physical constraint.
- Inertia is the worst enemy of a process of ongoing improvement. Solutions tend to assume a mass of their own that resists further change.
- Ideas are not solutions.

Figure 1.7 Partial list of TOC principles.

component optima. We saw this in the production example earlier. If all the components of a system are performing at their maximum level, the system as whole will not be performing at its best.

Cause and Effect

All systems operate in an environment of cause and effect. Something causes something else to happen. This cause-and-effect phenomenon can be very complicated, especially in complex systems.

Undesirable Effects and Critical Root Causes

Nearly all of what we see in our systems that we don't like are not *problems*, but *indicators*. They are the resultant effects of underlying causes. Treating an undesirable effect alone is like putting a bandage on an infected wound: It does nothing about the underlying infection, so its remedial benefit is only temporary. Eventually the indication resurfaces, because the underlying problem causing the indication never really went away. Eliminating undesirable effects gives a false sense of security. Identifying and eliminating a critical root cause not only eliminates all the undesirable effects that issue from it, but also prevents them from returning.

Solution Deterioration

An optimal solution deteriorates over time as the system's environment changes. Goldratt once said, "Yesterday's solution becomes today's historical curiosity." ("Isn't that interesting?! Why do you suppose they ever did that?") A process of ongoing improvement is essential for updating and maintaining the efficiency (and effectiveness) of a solution. Inertia is the worst enemy of a process of ongoing improvement. The attitude that, "We've solved that problem—no need to revisit it" hurts continuous improvement efforts.

Physical vs. Policy Constraints

Most of the constraints we face in our systems originate from policies—how we deliberately choose to operate—not physical things. Physical constraints are relatively easy to identify and break. Policy constraints are much more difficult, but they normally result in a much larger degree of system improvement than does the elimination of a physical constraint.

An organization must have some means of combating the process by which people become prisoners of their procedures. The rule book becomes fatter as the ideas become fewer. Almost every well-established organization is a coral reef of procedures that were laid down to achieve some long-forgotten objective.

—John W. Gardner

Ideas Are *Not* Solutions

The best ideas in the world never realize their potential unless they're implemented. And most great ideas fail in the implementation stage.

THE FIVE FOCUSING STEPS OF TOC

This is the beginning of the prescriptive part of the Theory of Constraints. Goldratt developed five sequential steps to concentrate improvement efforts on the component that is capable of producing the most positive impact on the system.^{11:300-308}

1. Identify the System Constraint

What part of the system constitutes the weakest link? If it's a physical constraint, what policy is driving it?

2. Decide How to Exploit the Constraint

By "exploit," Goldratt means we should wring every bit of capability out of the constraining component as it currently exists. In other words, "What can we do to get the most out of this constraint without committing to potentially expensive changes or upgrades?"

NOTE: The constraint, if physical, is the one place in the chain where efficiency or productivity is paramount.

3. Subordinate Everything Else

After we've identified the constraint (Step 1) and decided what to do about it (Step 2), we adjust the rest of the system to a "setting" that will enable the constraint to operate at maximum effectiveness. We may have to "de-tune" some parts of the system, while "revving up" others. Inevitably, this means sacrificing the individual efficiencies of non-constraints to some extent. However, care must be taken to assure that deliberate "detuning" of a non-constraint doesn't actually turn it into the system constraint.

Once we've subordinated non-constraints, we must evaluate the results of our actions: Is the constraint still constraining the system's performance? If not, we've eliminated this particular constraint, and we skip ahead to Step 5. If it is, we still have the same constraint—and we continue with Step 4.

4. Elevate the Constraint

If we're doing Step 4, it means that Steps 2 and 3 weren't sufficient to eliminate the constraint. We have to do something more. It's not until this step that we entertain the idea of major changes to the existing system—reorganization, divestiture, capital improvements, or other substantial system modifications. This step can involve considerable investment in time, energy, money, or other resources, so we must be sure we aren't able to break the constraint in the first three steps.

It's not uncommon for organizations that are not cognizant of constraint theory to jump straight from Step 1 (Identify) to Step 4 (Elevate). The net effect is that more costs are incurred, usually unnecessarily, and that opportunities to wring better performance from the system at no additional cost are ignored or overlooked.

"Elevating" the constraint means that we take whatever action is required to eliminate the constraint. When this step is completed, the initial constraint is broken, but some new factor, within the system or outside of it, becomes the new system constraint.

5. Go Back to Step 1, But Beware of "Inertia"

If a constraint is broken at Steps 3 or 4 we must go back to Step 1 and begin the cycle again, looking for the next thing constraining our performance. If you'll recall the production example (see Figure 1.5), this is exactly what we did. After we broke the constraint at process Step C, we went back and found D, then E, then A, and, finally, the marketplace.

The caution about inertia reminds us that we must not become complacent; the cycle never ends. We keep on looking for constraints, and we keep breaking them. And we never forget that because of interdependency and variation, each subsequent change we make to our system will have new effects on those constraints we've already broken. We may have to revisit and update those solutions, too.

The Five Focusing Steps have a direct relationship with the four management questions pertaining to change: What's the standard, what to change, what to change to, and how to cause change? They tell us how to answer those questions.

To determine what to change, we look for the constraint. To determine what to change to, we decide how to exploit the constraint and subordinate the rest of the system to that decision. If that doesn't do the complete job, we elevate the constraint. The subordinate and elevate steps also address the question "how to cause the change."

"This is all well and good," you're probably saying, "but how do we convert these abstract steps into concrete actions we can take? And how do we know when we've had a positive impact on the system?" These are two key questions. Let's look at the second one first.

THROUGHPUT, INVENTORY, AND OPERATING EXPENSE

A burning question we must address is, “How do we know whether our constraint-breaking has had a positive effect on our overall system?” Another way of asking this same question is, “How do we measure the effects of local decisions on the global system?” Organizations have struggled with this question for years. The Theory of Constraints is particularly useful in this arena.

Part of the answer to the question lies in the TOC emphasis on fixing the weakest link (constraint) and ignoring, at least temporarily, the non-constraints. Most effective laboratory research involves quantifying the effect of a change in one variable by holding all the others constant—or as nearly so as possible. This is *sensitivity analysis*, and it’s particularly useful in determining how much of an outcome is attributable to a particular cause.

By doing essentially the same thing in our organizations (that is, working only on the constraint), we achieve two benefits: (1) we realize the maximum system improvement from the least investment in resources, and (2) we learn exactly how much effect improving a specific system component has on overall system performance. I suspect Deming would consider this “appreciation for a system”^{7:96} of the highest order.

Goldratt conceived a simple relationship for determining the effect that any local action has on progress toward the system’s goal. Every action is assessed by its effect on three system-level dimensions: Throughput, Inventory, and Operating Expense.^{11:58-62} Goldratt provides precise definitions of these terms (see Figure 1.8).

The concept of Throughput, Inventory/Investment, and Operating Expense has been referred to by several names: throughput accounting, constraints accounting, and cash flow accounting. Each of these terms is, in some way, descriptive of the desired function of these metrics. Unfortunately, a detailed examination of this approach is beyond the scope of this book. Readers are strongly encouraged to educate themselves about this crucial topic. The two best of several sources for doing so are *Management Dynamics* by John A. Caspari and Pamela Caspari² and *Throughput Accounting* by Steven M. Bragg.¹

Throughput (T)

Throughput is the rate at which the entire system generates money through sales.^{11:58-62} Another definition of Throughput is “all the money coming into the system.” In for-profit companies, Throughput is equivalent to marginal contribution to profit. In a not-for-profit organization or a government agency, the concept of “sales” may not apply. In cases where an organization’s Throughput may not be easily expressed in dollars, it might be defined in terms of the delivery of a product or service to a customer. Another way of thinking about Throughput is...

The world is not interested in the storms you encountered, but did you bring in the ship?

—William McFee

Figure 1.8 Definitions of Throughput, Inventory and Operating Expense.

Inventory/Investment (I)

Inventory and Investment are all the money the system invests in things it intends to sell, or all the money tied up within the system.^{12:58-62} Inventory includes the acquisition cost of raw materials, unfinished goods, purchased parts, and other “hard” items intended for sale to a customer. Investment includes the expenditures an organization makes in equipment and facilities. Eventually, obsolescent equipment and facilities will be sold, too, even if only at their scrap value. As these assets depreciate, their depreciated value remains in the “I” column, but the depreciation is added to Operating Expense (see the next section).

Operating Expense (OE)

Operating Expense is all the money the system spends turning Inventory into Throughput. In other words, it’s the money going out of the system.^{12:58-62} Direct and indirect labor, utilities, interest, and the like are examples of operating expenses. Depreciation of assets is also considered an Operating Expense, because it constitutes the value of a fixed asset expended, or “used up,” in turning Inventory into Throughput.

Goldratt contended that these dimensions are interdependent. That is, a change in one will usually automatically result in a change in one or both of the other two. Let’s consider that for a minute. If you increase Throughput by increasing sales, Inventory and Operating Expense will also increase. Why? Because you’re likely to need more physical inventory to support increased sales, and you’re likely to spend more, in variable costs, to produce more. It’s also possible to make more money (if that’s your goal) without increasing sales. How? If you can produce the same sales revenues with less physical inventory, and spend less on Operating Expense doing it, you get to keep more of the money coming into the company (net profit).

So what would you, as a manager, try to do to improve your system? Obviously, you would increase Throughput while decreasing Inventory and Operating Expense. And here we have the key to relating local decisions to the performance of the entire system. As you decide what action to take, ask yourself these questions:

- Will it increase Throughput? If so, how?
- Will it decrease Inventory? If so, how?
- Will it decrease Operating Expense? If so, how?

If the answer to any of these questions is “yes,” go ahead with your decision (as long as doing so doesn’t compromise one or more of the other two), confident that the overall system will benefit from it. If you’re not sure, perhaps you’d better re-evaluate. The bottom line is that if it doesn’t eventually result in increased Throughput, you’re wasting your time—and probably your money.

Which Is Most Important: T, I, or OE?

To improve your system, where should you focus your efforts? On T, I, or OE? Consider the example in Figure 1.9. The choices are to focus on decreasing OE, decreasing I, or increasing T.

As you look at the graph, note that the theoretical limit in reducing OE and I is zero. A system can’t produce output with no physical inventory and no Operating Expense, so the practical limits of I and OE are somewhat above zero. Theoretically, there’s no upper limit to how high you can increase T, but from a practical standpoint there is a limit to the size of your market. But still, it’s highly probable that the potential for increasing T will always be much higher than the potential for decreasing I and OE. Consequently, it makes

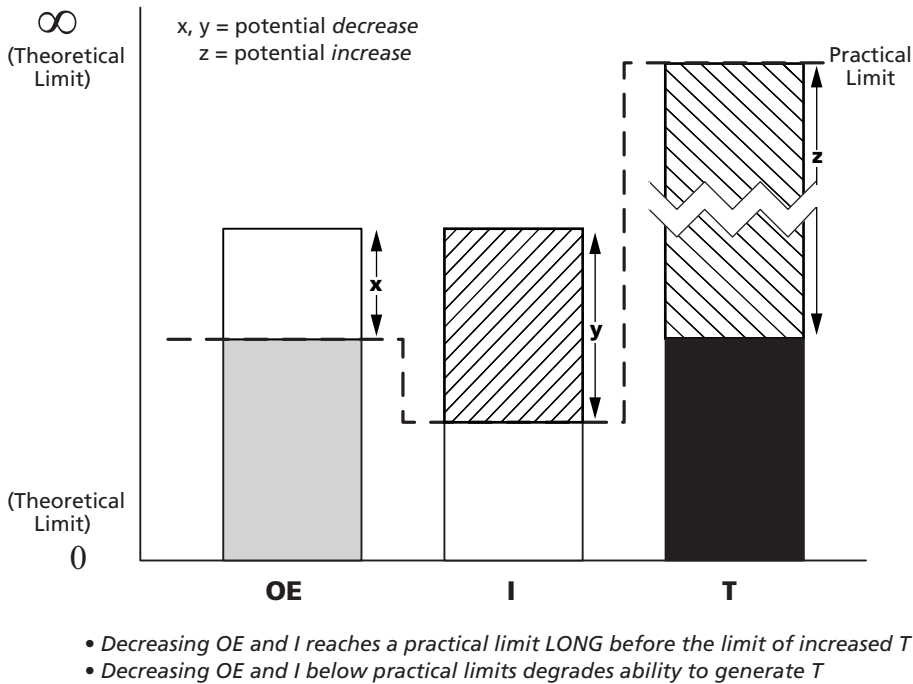

Figure 1.9 Limits to T, I, and OE.

sense to expend as much effort as possible on activities that tend to increase T, and make reduction of I and OE a secondary priority (see Figure 1.10).

But what's the normal priority of most companies in a competitive environment? Cut costs (Operating Expense) first. Then, maybe, reduce physical inventory (often without considering how far it can be reduced without hurting Throughput). And finally, try to increase throughput directly.

T, I, and OE: An Example

A classic example is the American aerospace defense industry. Traditionally, these companies have depended on huge government contracts to keep them going. As the defense budget dramatically declined in the early 1990s, fewer contracts were awarded, and for much smaller production runs. In most cases, the remaining defense business of these companies was not enough to keep the organization, as originally structured, afloat. So what was the response of these companies? Most took the traditional approach to some extent: cut fixed costs (Operating Expense). They laid off thousands of workers. Some

Figure 1.10 Management priorities with T, I, and OE.

even reduced Investment by selling off plants, warehouses, or other physical assets. But even that wasn't enough for certain companies, so they merged with others to "strengthen" their capacity to bid for whatever defense business remained. A few companies, however, have seen the handwriting on the wall. With the bottom not yet in sight, they couldn't continue to cut physical inventory or Operating Expense, so they opted to do what they probably should have done in the first place: look for ways to increase Throughput.

How? By finding new market segments for their core competencies, markets that don't depend on government contracts. One satellite builder found a market for its data technology in credit reporting and for its electronic technology in the automotive industry. Another defense electronics firm diversified into consumer communications: home satellite television and data communication. In both cases, the companies found new ways to increase Throughput, rather than just reducing Operating Expense and Inventory.*

T, I, and OE in Not-for-Profit Organizations

A common question often asked is, "What about organizations in which 'making more money, now and in the future' isn't the goal—as with charitable foundations, government agencies, and some hospitals? How do T, I, and OE apply to them?"

It's true that Goldratt conceived of Throughput, Inventory (or Investment), and Operating Expense as ways to measure an organization's progress toward its goal. However, when he created these measures, he was focusing exclusively on for-profit companies. In such organizations, money is an effective surrogate measure for almost all critical aspects of system-level performance, especially those pertaining to the organization's goal.

But it's clearly different in the case of a not-for-profit or government agency. Since that kind of organization's goal is *not* to "make more money, now and in the future," the financial expression of Throughput loses significance. So, how can we measure progress toward our goal if we're a not-for-profit organization?

A variety of alternatives has been suggested to modify expressions of T, and the variable elements of I, so that they accurately reflect progress toward a non-monetary goal. The problem with almost all of these alternatives is that they're contrived—an attempt to fit not-for-profits into a "metrics box" they were never intended to occupy.

Goldratt himself has offered what may be the best solution to the problem of assessing the progress of not-for-profits toward their goals. In July of 1995 he made the following observations.¹⁸ Figure 1.11 illustrates his concept.

Universal Measures of Value

In recorded history, money has been the closest thing to a universal measure of value that humankind has ever created. Where it applies completely, it's very effective. But because it's not always a valid measure of value, and since no other universal non-monetary measure of value has been invented, a different scheme for not-for-profits should be employed.

Goldratt suggested a dual approach. Operating Expense is still measurable in monetary terms; inventory, only partially so; and Throughput, not at all. Inventory, he proposed, should be differentiated as either "passive" or "active."

* A more detailed treatment of T, I, and OE can be found in three other sources: *The Haystack Syndrome*¹² by Goldratt and *Management Dynamics*² by the Casparis and *Throughput Accounting*¹ by Bragg. (1990, 2004, and 2007 respectively).

Figure 1.11 T, I, and OE in a not-for-profit organization.

Passive Inventory

Passive inventory, as the name implies, is acted upon. In the manufacturing model, passive inventory would be the raw materials that are converted into Throughput. But in a not-for-profit (a hospital, for example), passive inventory isn't measurable in monetary terms because the "raw materials" are often people. Figure 1.11 shows customers (patients) going through the non-monetary side of the system and becoming "Throughput": well people.

Active Inventory (Investment)

Active inventory might actually be better defined as *investment*. It is measurable in monetary terms, because it constitutes the facilities, equipment, and tangible assets that act upon the passive inventory. This part of the inventory is shown in the upper right portion of the system in Figure 1.11.

So how should managers of not-for-profits adjust their focus? In principle, the emphasis remains the same: increase Throughput, limit Investment, and decrease Operating Expense—in that order. In practice, Investment and Operating Expense—both expressed in monetary terms—are managed the same way they are in for-profit companies. The difference arises in how we should manage Throughput and passive inventory.

Managing T Through Undesirable Effects

Without a universal non-monetary measure of value, Goldratt maintained that measuring T and passive I in not-for-profits isn't ever likely to be practical. So, he says, don't bother trying to do it. Instead, work on eliminating the undesirable effects (UDE) associated with

Throughput. (Refer to Chapter 4, “Current Reality Trees,” for a thorough discussion of undesirable effects and their relationship to root causes.) Use UDEs as your indicators of progress. As you eliminate them, progress toward the organization’s goal can be assumed.

In summary, a not-for-profit should search out and correct the causes of UDEs affecting Throughput, while keeping the costs of Investment and Operating Expense down (refer to Figure 1.11). But the primary emphasis should always be on the former, not the latter.

NOTE: Many people will inevitably ask, “What about the operating budget of a not-for-profit? Where does that fit into the T, I, and OE formulation?” It isn’t in Throughput, because production efforts aren’t aimed at increasing it. And it isn’t really an Operating Expense alone, because some part of it is spent on capital improvements, which are really Inventory (Investment). The answer, according to Goldratt, is that the annual operating budget should be considered a *necessary condition*. Efforts to reduce active Inventory and Operating Expense will naturally have a beneficial effect on the annual budget. But the budget is the means to an end—a necessary condition—not the goal.

THE TOC PARADIGM

The Theory of Constraints is considerably more than just a theory. In effect, it’s a paradigm, a pattern or model that includes not only concepts, guiding principles, and prescriptions, but tools and applications as well.

We’ve seen its concepts (systems as chains; T, I, and OE) and its principles (cause and effect, local vs. system optima, and so on). We’ve examined its prescriptions (the Five Focusing Steps; what to change, what to change to, how to change). To complete the picture, we’ll consider its applications and tools.

Applications and Tools

Each application of TOC starts out being unique. As the theory is applied in a new situation, it creates a distinctive solution. Often, however, such solutions can be generalized to a variety of other circumstances.

Drum-Buffer-Rope

For example, in *The Goal*, Goldratt describes a TOC solution to a production control problem in a specific plant of a fictitious company. This solution became the basis for a generic solution applicable to similar production situations in other industries. Goldratt called this production control solution “drum-buffer-rope.”^{5,13,17} Many companies have applied this solution, originally developed to solve one company’s problem, with great success. Consequently, drum-buffer-rope, which began as an application of TOC principles, has become a tool in the TOC paradigm.

Critical Chain Project Management

A natural extension of the drum-buffer-rope concept to project management is called critical chain.^{9,14,15,16} Whereas production is repetitive, projects are usually one-time deliveries; some of the elements of drum-buffer-rope required modification before they could be applied to managing projects. But the basics are similar. Critical chain, perhaps to an even greater extent than drum-buffer-rope, has become a widespread way of ensuring shorter project durations and a higher probability of delivering them on time.

Replenishment and Distribution

Just as the drum-buffer-rope concept was extended to project management, so too has it been applied to manufacturers' raw material acquisition management and finished goods distribution. Combined with drum-buffer-rope, the TOC replenishment and distribution tool can make for a fast, streamlined supply chain. As of this writing, there is not much formally published about it beyond a few conference papers.

Throughput Accounting

Another tool is called Throughput accounting. This is a direct outcome of the use of Throughput, Inventory, and Operating Expense as management decision tools, as opposed to traditional management cost accounting.^{1,2} Throughput accounting basically refutes the commonly used concept of allocating fixed costs to units of a product or service. While the summary financial figures remain essentially the same, the absence of allocated fixed costs promotes very different management decisions concerning pricing and marketing for competitive advantage. In other words, Throughput accounting is a much more robust approach for supporting good operational decisions than standard cost accounting. As with drum-buffer-rope production control, throughput accounting began as a specific solution to one company's system performance measurement problem and ended up applicable to any company's measurement problems.

The Logical Thinking Process

The Thinking Process Goldratt developed to apply TOC is logical by nature. The drum-buffer-rope, critical chain project management, supply chain, and throughput accounting tools all have foundations in the logic of cause and effect. But that logic isn't necessarily intuitive, and it certainly doesn't spring fully formed, like Pegasus from the head of Medusa. Rather, this logic finds its expression in another TOC tool—the most universal of them all—the Logical Thinking Process.

The Thinking Process comprises six* distinct logic trees and the "rules of logic" that govern their construction. The trees include the Intermediate Objectives Map, the Current Reality Tree, the Evaporating Cloud, the Future Reality Tree, the Prerequisite Tree, and the Transition Tree. The rules are called the Categories of Legitimate Reservation. These trees, the Categories of Legitimate Reservation, and how to use them, are the subject of this book.

THE INTERMEDIATE OBJECTIVES MAP

The Intermediate Objectives (IO) Map is a "destination finder." Stephen R. Covey contends that one should always begin any endeavor with the end in mind.^{4,95} The IO Map (see Figure 1.12) helps problem solvers to do that.

* Originally, Goldratt conceived of only five tools. In the mid-1990s, he briefly dabbled with the idea of another logical aid he referred to as an Intermediate Objectives (IO) Map, but he never continued with a concerted effort to develop and use it. In my strategy development work, I found the IO Map to be not just useful, but critical to success. (See Dettmer, *Strategic Navigation*, Quality Press, 2003.)⁸ It became apparent that it was equally useful for the kind of system problem solving for which the Thinking Process was originally conceived. The IO Map concept is fully developed, explained, and illustrated in this edition for the first time.

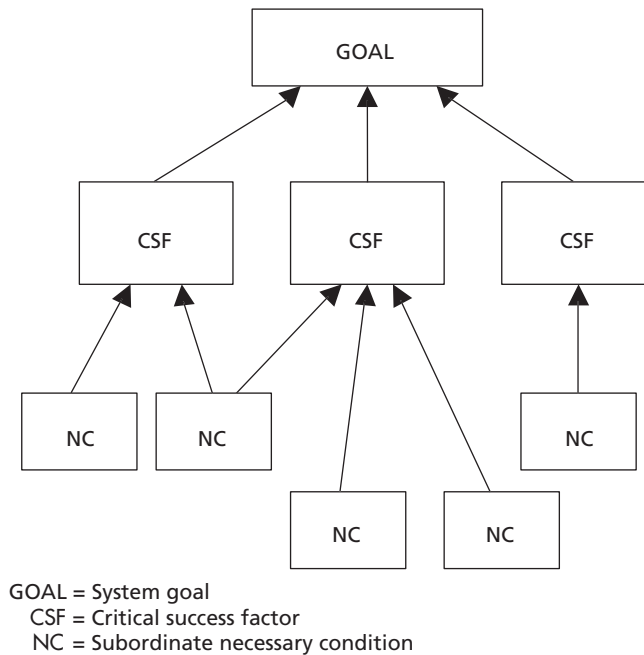

Figure 1.12 The Intermediate Objectives Map.

It begins with a clear, unequivocal goal statement and the few critical success factors that are required to realize it. It then provides a level or two of detailed necessary conditions for achieving those critical success factors.

These elements are structured in a tree that represents the normative situation for the system—what *should* be happening, or what we want to be happening. The IO Map provides the benchmark for determining how big the deviation is between what is happening in the system and what should be happening. Chapter 3 describes the IO Map in detail and provides comprehensive instructions for constructing one.

THE CURRENT REALITY TREE

The Current Reality Tree (CRT) is a gap-analysis tool (see Figure 1.13). It helps us examine the cause-and-effect logic behind our current situation and determines why that situation is different from the state we'd prefer to be in, as expressed in the IO Map.

The CRT begins with the undesirable effects we see around us—direct comparisons between existing reality and the terminal outcomes expressed in the IO Map. It helps us work back to identify a few critical root causes that originate all the undesirable effects we're experiencing. These critical root causes inevitably include the constraint we're trying to identify in the Five Focusing Steps.

The CRT tells us *what* to change—the one simplest change to make that will have the greatest positive effect on our system. Chapter 4 describes the Current Reality Tree in detail and provides comprehensive instructions and examples on how to construct one.

THE EVAPORATING CLOUD: A CONFLICT RESOLUTION DIAGRAM

Goldratt designed the Evaporating Cloud (EC), which amounts to a conflict resolution diagram, to resolve hidden conflicts that usually perpetuate chronic problems (see Figure 1.14). The EC is predicated on the idea that most core problems exist because some underlying tug-of-war, or conflict, prevents straightforward solution of the problem; otherwise, the problem would have been solved long ago. The EC can also be a “creative engine,” an idea generator that allows us to invent new, “breakthrough” solutions to such nagging problems. Consequently, the EC answers the first part of the question, what to change to. Chapter 5 describes the Evaporating Cloud in detail.

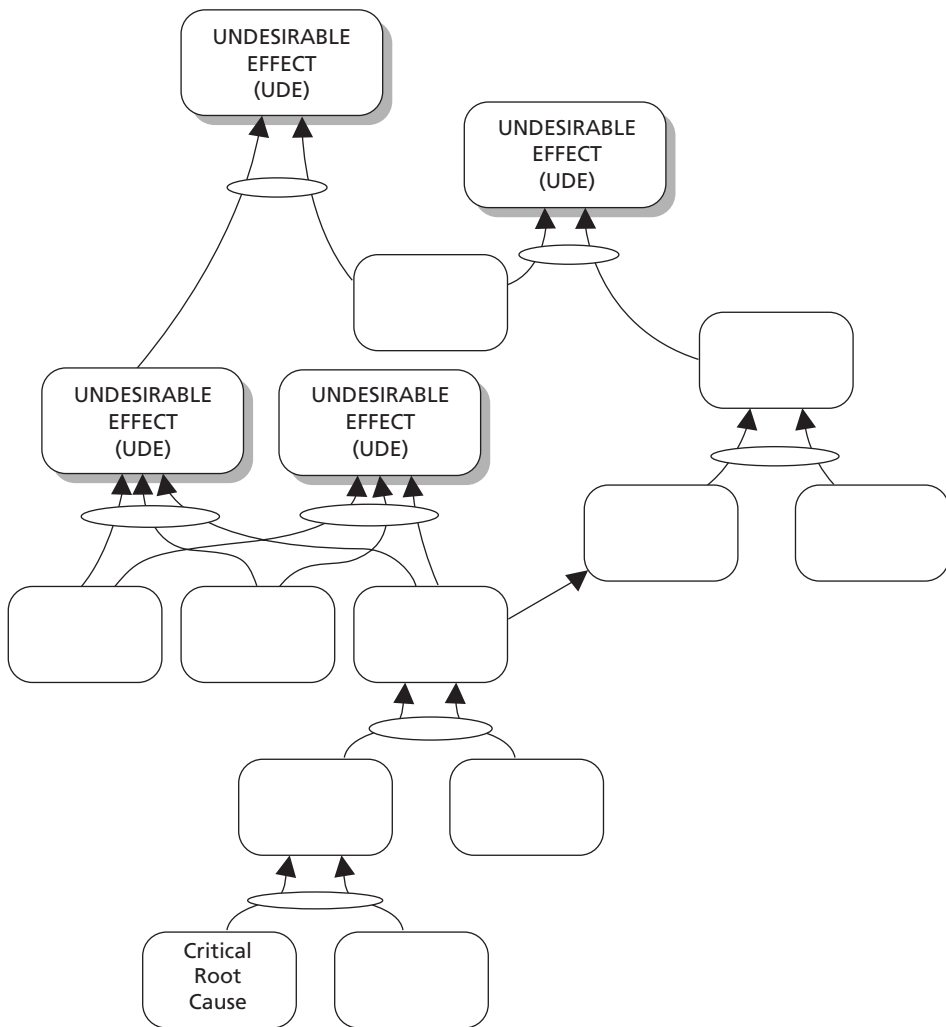

Figure 1.13 The Current Reality Tree.

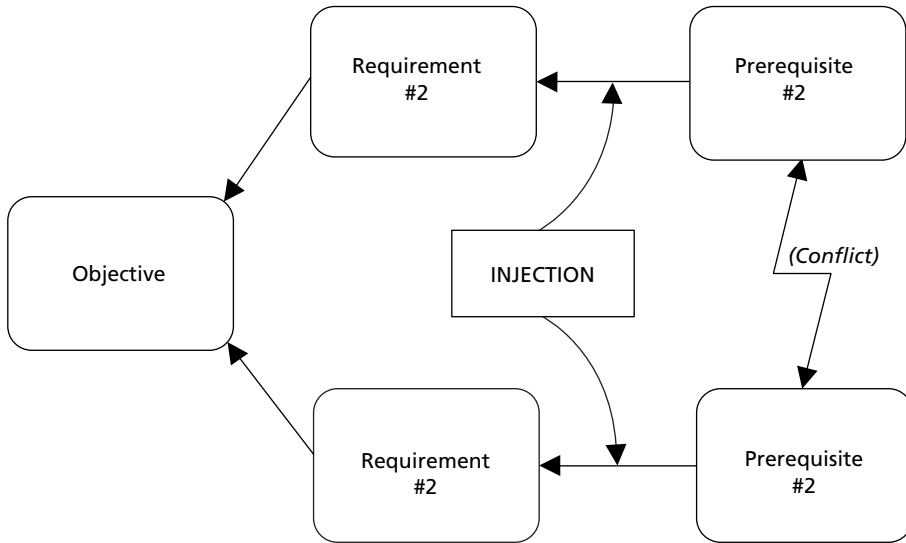

Figure 1.14 The Evaporating Cloud (conflict resolution diagram).

THE FUTURE REALITY TREE

The Future Reality Tree (FRT) serves two purposes (see Figure 1.15). First, it allows us to verify that an action we'd like to take will, in fact, produce the ultimate results we desire. Second, it enables us to identify any unfavorable new consequences our contemplated action might have, and to nip them in the bud.

These functions provide two important benefits. We can logically “test” the effectiveness of our proposed course of action before investing much time, energy, or resources in it, and we can avoid making the situation worse than when we started.

This tool answers the second part of the question—what to change to—by validating our new system configuration. The FRT can also be an invaluable strategic planning tool. Chapter 6 describes the Future Reality Tree in detail, providing examples and comprehensive instructions on how to create one.

THE PREREQUISITE TREE

Once we've decided on a course of action, the Prerequisite Tree (PRT) helps implement that decision (see Figure 1.16). It tells us in what sequence we need to complete the discrete activities in implementing our decision. It also identifies implementation obstacles and suggests the best ways to overcome those obstacles. The PRT provides the first part of the answer to the last question, how to change. Chapter 7 describes the Prerequisite Tree in detail and provides both examples and comprehensive procedures for constructing one.

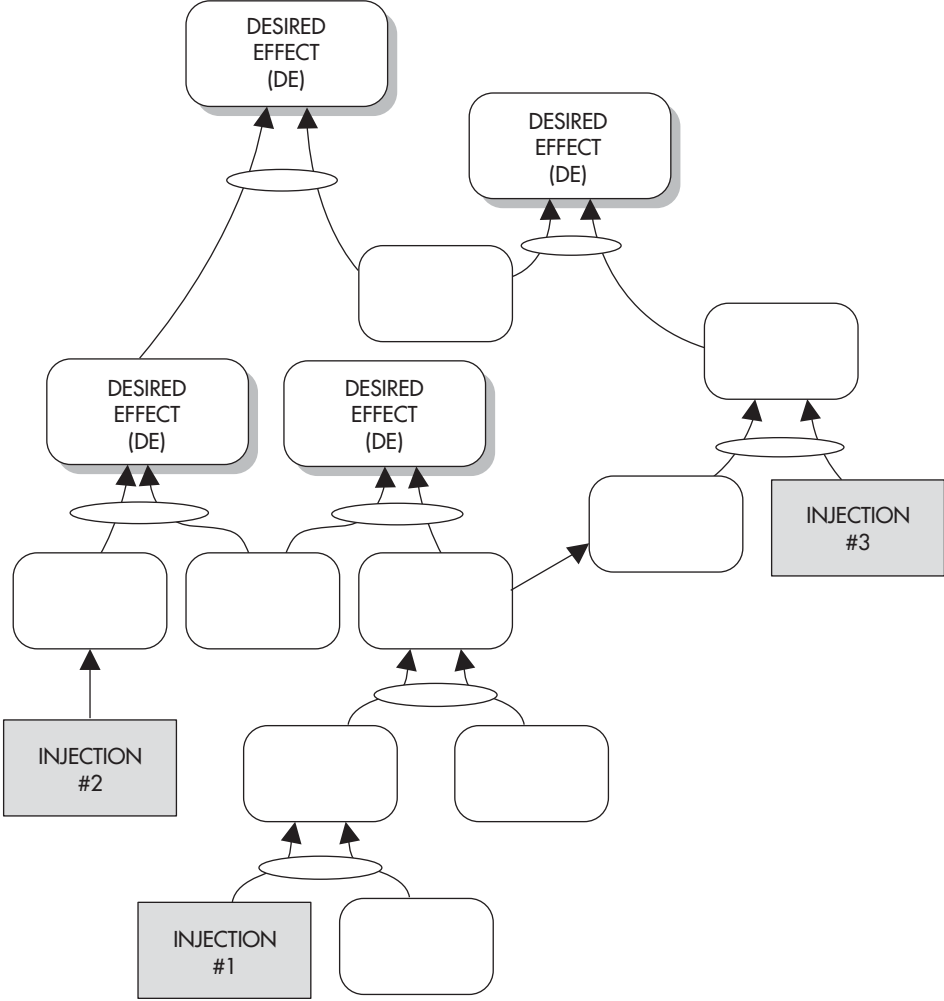

Figure 1.15 The Future Reality Tree.

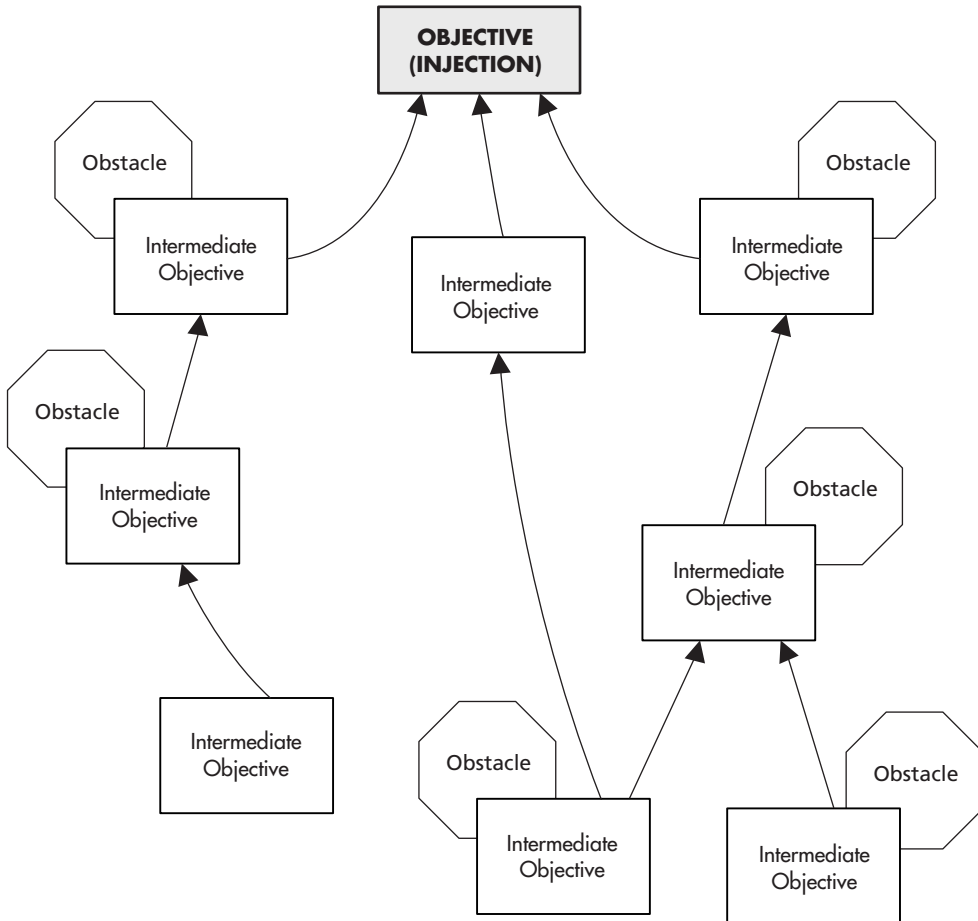

Figure 1.16 The Prerequisite Tree.

THE TRANSITION TREE

The last of the six logical tools is the Transition Tree (TT) (see Figure 1.17). The TT was designed to provide detailed step-by-step instructions for implementing a course of action. It provides both the steps to take (in sequence) and the rationale for each step. The TT could be considered a detailed road map to our objective. It answers the second part of the question, how to change. Chapter 7 also describes the Transition Tree.

NOTE: With this edition, a comprehensive examination of the Transition Tree and instructions for constructing it are omitted. A historical perspective for doing so is provided in Chapter 7. Instead of a Transition Tree, a three-phase project management approach to implementing policy changes is introduced.

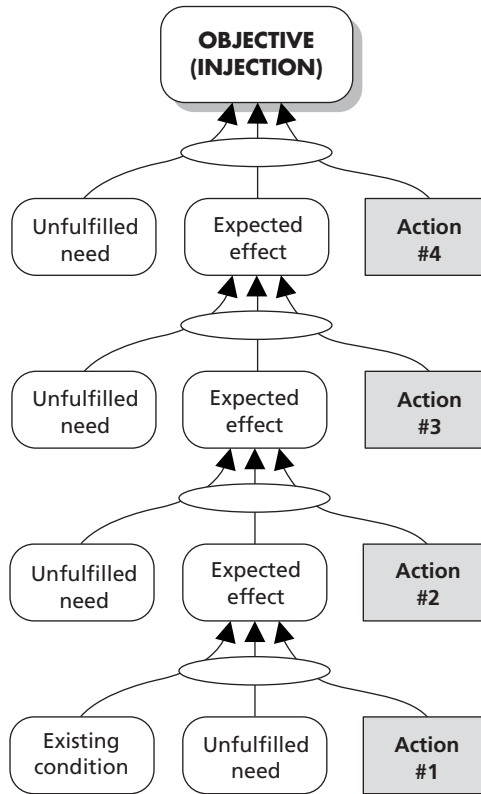

Figure 1.17 The Transition Tree.

THE CATEGORIES OF LEGITIMATE RESERVATION

The Categories of Legitimate Reservation (CLR) are the “logical glue” that holds the trees together. Essentially, they are eight rules, or tests, of logic that govern the construction and review of the trees. To be logically sound, a tree must be able to pass the first seven of these tests. The eight CLR include:

1. Clarity
2. Entity existence
3. Causality existence
4. Cause sufficiency
5. Additional cause
6. Cause-effect reversal
7. Predicted effect existence
8. Tautology (circular logic)

We use the CLR as we construct our trees to ensure that our initial relationships are sound. We use the CLR after the tree is built to review it as a whole. We use the CLR to scrutinize and improve the trees of others (and they to review ours). And, most important, we use the CLR to communicate disagreement with others in a non-threatening way, which promotes better understanding rather than animosity. Chapter 2 describes the CLR in detail, gives examples of their application, and provides instructions on how to scrutinize your own trees as, or after, you build them.

THE LOGICAL TOOLS AS A COMPLETE “THINKING PROCESS”

Each of the six logical tools can be used individually or they can be used in concert, as an integrated “thinking process.” Recall that earlier we discussed TOC as a methodology for managing change. The four basic questions a manager must answer about change (what is the standard, what to change, what to change to, and how to cause the change) can be answered using the logical tools as an integrated package. Figure 1.18 shows the relationship of the logical tools to the four management questions about change.

State of Change	Applicable Logic Tree
What’s the desired <i>standard</i> ?	Intermediate Objectives Map
<i>What</i> to change?	Current Reality Tree
What to change <i>to</i> ?	Evaporating Cloud, Future Reality Tree
<i>How</i> to cause the change?	Prerequisite Tree, Transition Tree

Figure 1.18 How the logic trees relate to four management questions about change.

Figure 1.19 shows a general overview of how each tool fits together with the others to produce an integrated thinking process. Non-quantifiable problems of broad scope and complexity are particularly prime candidates for a complete thinking process analysis. The rest of this book is devoted to explaining how the six logic trees and the Categories of Legitimate Reservation are used.

It is wise to keep in mind that no success or failure is necessarily final.

—Unknown
